Aplications

2. **Configuration management:**
   - We will tell Ansible what we want, not how to get there.
   - For example, install some OS patches and the install a programming language, and then MySQL. For this we need a **playbook**.
   - A Playbook is a set of tasks. We want to run this aginst all of our hosts and run e.g., a security patch, and make sure all run the same version of the patch.
   - A Playbook requires three things: (1) a name of that play, (2) the host or group of hosts where is going to run against, and (3) the actual tasks.
   - A Playbook is written in YAML which is a declarative language.
   - Agent-Less: No need to install any agent on the VMs that were provisioned. Ansible takes advantage of SSH.
